ABSTRACT

Introduction: Hospitals collect and store massive amounts of data. Developing better 'Information Systems' to manage these data more efficiently had been a challenge during the past decades, and automation was considered by many as the way forward.

Method: An interventional project with predominantly qualitative methodology was carried out to implement and then assess a manual and computer-based intervention for management of midnight data at Base Hospital, Horana. Key Informant Interviews, Focus Group Discussions, and document reviews were the key components of the qualitative arm of the study. A satisfaction survey was subsequently conducted among the nursing staff, and selected indicator values were measured pre and post-implementation.

Results: Following the pre-interventional analysis, the modified data management system was introduced to address the gaps in the system. The post-interventional analysis revealed that the modified system has better and user-friendly collecting, reporting and analysing tools, enhanced data dissemination capabilities and favourable outcome with the inbuilt system to identify data errors. Satisfaction among the nursing staff demonstrated visible improvement.

Conclusion: The study recommends a gradual introduction of process modification and automation of the midnight data management system at Base Hospital Horana.

Keywords: Midnight Report, Hospital Information Systems, Evidence-Based Decision Making

INTRODUCTION

A large amount of data is collected in hospitals each day⁽¹⁾. During the past decades, demand for 'Information Systems' which are better equipped to collect, process and analyse reliable data has risen rapidly⁽²⁾. In 1991, a report from the General Accounting Office of United States stated that automated records could significantly enhance patient management by providing more accurate, higher quality, readily accessible information to support evidence-based decision-making⁽³⁾.

High cost, underdeveloped technology, difficulties in adapting to change and security concerns are key challenges to overcome when developing information systems. Balaraman and Kosalram (2013) mentioned support from the top, introduction of user-friendly systems and training as key ingredients for success⁽⁴⁾.

In Sri Lanka, the system of medical record keeping is predominantly paper-based, placing heavy pressure on healthcare workers⁽⁵⁾. Even though there were isolated projects where process automation was integrated, no large-scale e-Health projects had been implemented so far in the country⁽⁶⁾. In 2015, a Health Information Management System (HIMS) was implemented in the Outpatient Department at Base Hospital Horana (BHH). The plan was to expand the automation gradually, to enhance hospital data management. However, the process has been stalled since its inception. As a result, a significant proportion of generated data, including Midnight Data, lies dormant in their raw form, unused⁽⁷⁾.

OBJECTIVES

The objective of the study was to implement and then assess an intervention for management of hospital Midnight Data to enhance evidence-based decision making on patient care services at Base Hospitals, Horana (BHH). The intervention comprises manual and computer-based process modification and automation.

METHODOLOGY

The project followed an interventional design. The limited number and diverse nature of individuals involved in the process and the specialised nature of each individual's responsibility demanded a predominantly qualitative methodology.

Triangulation was used, a technique used in qualitative studies which is a proven and efficient design. Aim of achieving saturation point was used as a method of ensuring collection of complete data. Framework thematic analysis⁽⁸⁾ and Bowens' method of document review were used for data analysis⁽⁹⁾.

Purposively selected interviewees were included in the Key Informant Interviews (KII) and Focus Group Discussions (FGD). The saturation level determined the sample size for each phase of the study.

The project was conducted in three phases;

1 Phase 1

A pre-interventional study was conducted to describe the existing process of Midnight Data management and identify gaps in the system. A total of nine KII and two FGD were conducted with individuals involved in the process.

2 Phase 2

A hybrid technique was adopted where a manual and computer-based Data Management System was designed and implemented. Before implementation, discussions were held with the relevant stakeholders, and implementation schedule was agreed upon. Introductory and training sessions were conducted for the relevant officers. New data collecting, reporting and analysing tools were introduced, and the modified process was explained during these sessions.

Through the first two weeks in operation, minor alterations and modifications were made to the system to enhance operability.

3 Phase 3

The outcome of the implemented system was assessed to determine its' ability to improve the management of

Midnight Data and to enhance the evidence-based decision-making process.

a) The same individuals interviewed in phase 1 were re-interviewed.

b) A satisfaction survey was conducted among the nursing staff using a self-administered questionnaire. Participants were requested to compare the pre and post-intervention processes.

c) Selected indicators were measured for pre and post comparison.

Ethical Clearance for this study was obtained from the Ethics Review Committee of the Postgraduate Institute of Medicine, University of Colombo, Sri Lanka.

RESULTS

1 Phase 1- Pre-Intervention

1.1 Current Process

All inward patients were admitted to the Preliminary Care Unit (PCU) where a Bed Head Ticket (BHT) was issued. As patients progress from admission to discharge, details were entered in several books/ registers (data collecting tools) as illustrated in Figure 1.

Summary data extracted from these books/ registers were used to create two reports.

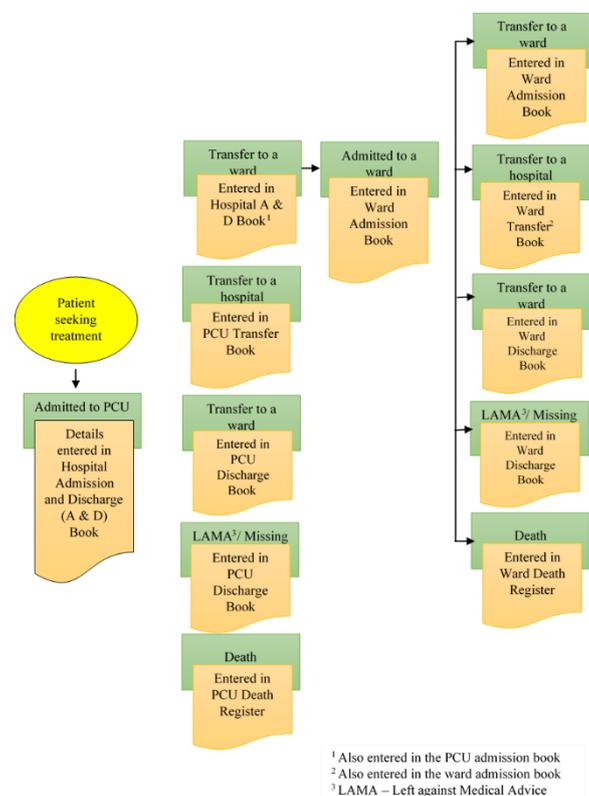

Figure 1: Patients' progress from admission to discharge and process of data collection

Data Collection Form for the Mid Night Report (Ward/ Unit), Base Hospital, Horana			
Individual Patient Summaries			
Report Date	Name		Sex
	Date/ Time of Admission	Age Ward	BHT

Structured Format Introduced

Figure 6: MNR reporting form for 'Individual Patient Summaries'

In addition, datasheet graphically visualised the admissions, discharges (as bar charts), trends of Communicable Diseases (as line graphs), and other key information as tables.

2.4 Step 4

The 'Individual Patient Summaries' written by ward nurses in ward MNRs were attached to the hospital MNR (eliminating duplication). The Midnight Data were entered into the new analysis sheet daily. Data visualisation sheets were presented to the Medical Superintendent, together with the MNR. Summary data were e-mailed to Regional directors' office monthly.

	Monthly Total	Per Day Average
Hospital		
Total Admissions	0	#DIV/0!
Inpatient service days	0	#DIV/0!
Total Discharges*	0	#DIV/0!
Total transfers from other hospitals	0	#DIV/0!
Total transfers to other hospitals	0	#DIV/0!
Death within 48h	0	#DIV/0!
Death after 48h	0	#DIV/0!
Total deaths	0	#DIV/0!
Total LAMA	0	#DIV/0!
Total missing	0	#DIV/0!
WD 1		
Total Admissions	0	#DIV/0!

	PCU	1	2 & 3
Inpatient service days (for a period)	0	0	0
Average Daily inpatient census	#DIV/0!	#DIV/0!	#DIV/0!
Average length of stay	#DIV/0!	#DIV/0!	#DIV/0!
Inpatient bed occupancy rate (%)	#DIV/0!	#DIV/0!	#DIV/0!
Bed Turnover rate (%)	#DIV/0!	#DIV/0!	#DIV/0!
Death Rates(%)	#DIV/0!	#DIV/0!	#DIV/0!

Figure 8: Auto-generating key indicators

3 Phase 3: Post Intervention Analysis

3.1 KIIs and the FGDs

Post interventional KIIs and the FGDs were also analysed using the same framework used in the pre-interventional stage.

1. Not having to rewrite the 'patient summaries' gave sisters time to pay more attention to nursing care supervision.
2. The reporting formats were pronounced as being 'very easy, uniform and well organised'.

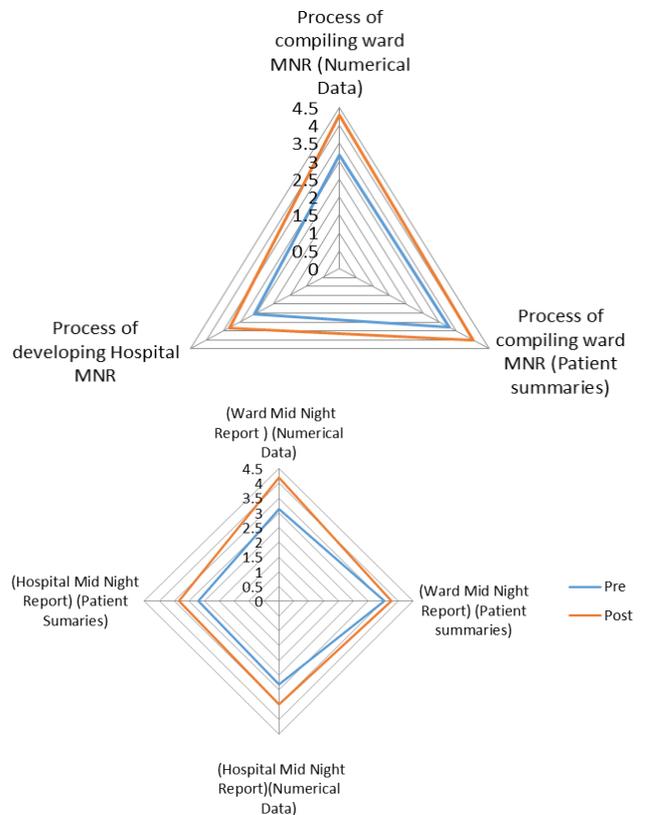

Figure 9: Participants' satisfaction towards data collecting/ reporting tools and data management process

3. 'Patient Summaries' were well received by the administrators' this is what we wanted. Clear, short summaries'
4. Uniformity of MNRs and the similarity to the analysis sheet made the data entry process as 'very easy and fast'.
5. Satisfaction was expressed regarding error identification, data visualisation and the auto-generation of basic indicators. 'We don't have to do them manually; it is easy. Less errors'.
6. Graphs showing disease trends were stated as extremely useful. 'If a graph shows an increase, we can act early'.
7. Matrons used staff data to relocate nurses during the night shift according to the workload.
8. Provisions to identify errors were described as 'one of the best changes' and the collection of 'Same Day Discharges' allowed to 'show the entire workload done'.

Discussion of hospital statistics at the Management Committee Meetings and weekly summaries received by the RDHS office was perceived as extremely satisfying.

3.2 Changes in selected indicators:

Table 1 gives pre and post-intervention values of selected variables demonstrating the changes in data quality, dissemination and decision making.

3.3 Results of the satisfaction survey:

Results illustrated in Figure 9 demonstrate an increased level of satisfaction in the post interventional stage in all domains.

DISCUSSION

Introduction of automation has proven to be an effective method of enhancing data management process as demonstrated by many authors.

However, in Sri Lanka, the process has been slow and difficult. Many factors described in the literature, including the lack of funds, underdeveloped technology and human factors such as resistance to change and difficulties in adjusting to new technology may have stalled the process.

In this study, the satisfaction of those involved in the process showed an increase in multiple domains, as demonstrated by views expressed in KII and FGDs. Results of the satisfaction survey strengthen these views.

Pre and Post interventional stage results were compared, and an increase in data quality was evident. Errors were reduced by 77.78% during a period of one month. Previously unreported data were routinely reported with the new modifications. Data dissemination improved with more summary reports being delivered to the Regional Director of Health Services (Zero to five reports/ month). Increased use of data in resource allocation and identification of disease trends were also observed.

However, shortage of equipment and skilled human resources intended that the automation could only be introduced at a later stage in the process. It was this same realisation that made the project to adopt gradual modifications rather than a complete overhaul.

The possibility of using data for decision making was embraced by the participants, as was evident in the interviews. Data collectors and reporters showed higher satisfaction with the ability of the process to increase data quality.

However, there are many documented factors leading to difficulties in adopting evidence-based decision-making processes. The inherited differences in the nature of the decisions, allotting of higher value for experience, and self-taught knowledge to decision making are among them⁽¹⁰⁾. These are likely to be prevalent among BHH managers. However, in contrast to what is described in the literature, top and middle-level managers in Sri Lanka has a medical or nursing background. This could have contributed to the

Table 1: Pre and post-intervention values of selected variables

Variable	Pre-Intervention	Post-Intervention
Number of 'Same Day Discharges' reported during one month	None	30
Number of erroneous Midnight Reports submitted during one month (Errors in the difference between calculated MNR and census results)	9	2
Number of summary reports sent to the RDHS during one month	None	5
Number of management committee meetings where hospital data were discussed	None (two meetings considered)	1

faster adoption of the modified system. As suggested by the World Health Organization (WHO), training and awareness programs may have also played a vital role in the change management process⁽¹¹⁾.

CONCLUSIONS

Initially, the MNR compilation was time-consuming, and the reports contained many deficiencies. This project

introduced a user-friendly intervention with the involvement of stakeholders which improved the data quality, staff satisfaction and promoted data dissemination and evidence-based decision making. The study recommends the continuous upgrading of the Midnight data management system at BH Horana with the revitalisation of the stalled automation process.
