Abstract

Introduction
Recent developments in the field of ICT may have an impact on telemedicine. This systematic review aims to evaluate the recent clinical trials of telemedicine in relation to store-and-forward, real time and remote monitoring methods.

Method
Articles were obtained from November 2007 to November 2009 using the MEDLINE database. Studies reported on clinical trials were included and those indicating the use of telephony, electrical equipment and feasibility studies were excluded. Articles were abstracted and grouped for various disciplines for analysis.

Results
There were three large sample Randomised Control Trials (RCTs), nine small sample RCTs, four prospective studies, three retrospective studies, one cohort study, four case control studies, and fifteen descriptive studies. The three large sample RCTs have been reported one each in neurology, diabetes and dermatology.

Thirty nine articles selected were nine on neurology, four each on psychiatry, diabetes and cardiology, three each on ophthalmology and dermatology, two each on acute care, transplant and ENT and one each on child abuse, endoscopy, general practice, leprosy, nephrology and radiology.

After further exclusion, rest of the 27 articles revealed that the outcome had improved in 41%, comparable in 15%, benefited in 33% and not enhanced in 11% when telemedicine was compared to conventional approaches.

Conclusions
Most of studies reported have revealed advantages of telemedicine against conventional methods of care. However further large sample randomized controlled trials are necessary to confirm these results.

Keywords: Telemedicine, Clinical Trials

Introduction
Telemedicine is the use of information and communication technology to provide health care services to individuals who are at some distance from a selected health care provider \(^{(1)}\).

There are three major types of computer based telemedicine applications in terms of how the information is transferred:

a. Store-and-forward method in which recorded data is transferred offline
b. Real time method which involves online two way interactive videoconferencing
c. Remote monitoring method in which patients are monitored at a distance which can either be hospital or home based.

Telemedicine techniques have been adopted for various disciplines such as radiology, dermatology, cardiology, pathology, surgery, psychiatry, neurology, ophthalmology and
pharmacy (2).
Over the last few years, many aspects of information and communication technology seem to have changed worldwide and that is likely to have made an impact on telemedicine activities. Evidence on the effectiveness of telemedicine when compared to face-to-face care is sparse (3). Previous reviews on telemedicine have studied assessment methods, cost effectiveness and patient outcomes. In this paper an attempt has been made to review the clinical trials that used telemedicine interventions reported in the scientific literature during the last two years. This study would help to identify the key areas in which computer based telemedicine have been applied successfully recently.

Methods

Computerized literature searches were performed using the MEDLINE database for articles from November 2007 to November 2009. Inclusion criteria were the key words telemedicine, human, and clinical trial.

Exclusion criteria were the use of telephony, electrical equipment and feasibility studies. Each title and abstract was retrieved and reviewed. Full text articles also were studied where possible. Articles were classified according to the system by Jovell and Navarro-Rubio (1,4) (Table 1), where 9 levels are described in descending order of strength. Articles were then grouped into subsets according to the disciplines and analyzed for their content.

Table 1. Classification of studies (According to Jovell and Navarro-Rubio)

1. Meta analysis of randomized controlled trials (RCT)
2. Large sample randomized controlled trials
3. Small sample randomized controlled trials
4. Nonrandomized controlled prospective studies
5. Nonrandomized controlled retrospective studies
6. Cohort studies
7. Case-control studies
8. Non-controlled clinical series, descriptive studies, consensus methods
9. Anecdotes or case reports

Results

Literature searching yielded 64 articles. After screening for exclusion criteria, 39 articles were selected for the analysis. Of these, two were on store-and-forward method, twenty eight were on real time video conferencing and nine were on remote monitoring. With regard to the disciplines involved there were nine in neurology, four each in psychiatry, diabetes and cardiology, three each in ophthalmology and dermatology, two each in acute care, transplant and ENT and one each in child abuse, endoscopy, general practice, leprosy, nephrology and radiology. According to Jovell and Navarro-Rubio classification there were three large sample RCTs, nine small sample RCTs, four prospective studies, three retrospective studies, one cohort study, four case control studies, and fifteen descriptive studies. Details of interventions and outcomes of twenty seven studies for each discipline group in descending order of strength are given in Table 2. Rest of the studies representing individual miscellaneous disciplines were excluded.

### Neurology

Studies consisted of one large sample RCT, four small sample RCTs, one prospective trial and three case studies. The STROKE DOC study (3) which was a 5 year, 400 participant trial, comparing two modalities at four remote sites had shown that is feasible to perform site-independent stroke consultations. Small sample studies (6-9) and the prospective study (10) on tele-rehabilitation revealed increased efficiency of care, early discharge from hospital and long term benefit for stroke patients. Other three case studies (11-13) have presented innovative ways for post rehabilitation programmes.

### Psychiatry

The three retrospective studies (14-16) presenting computer based treatment for psychiatric disorders have shown that the outcome was found to be comparable to that of face-to-face methods. The case descriptive study (17) conducted on adolescent tele-psychiatry has concluded that parents were highly satisfied with the care given to their children.

### Diabetes

The other large sample RCT retrieved in this review (18) was the telemedicine case management on 1665 patients with usual care in older, ethnically diverse, medically underserved patients with diabetes mellitus which had resulted in net improvements in HgbA1c, LDL-cholesterol and blood pressure levels over a 5 year period in a group of medically underserved Medicare beneficiaries. The retrospective trial (19) based on delivering specialty advice did not reveal any reduction in diabetes related costs. Two other descriptive studies (20,21) reported favourable improvement in diabetes care due to by videoconferencing.

### Cardiology

Two prospective studies (22,23) on home based tele-monitoring in cardiac patients have shown that tele-medical home surveillance groups had reduced hospitalizations and significantly reduced anxiety levels compared to the control groups which did not receive the intervention. While a paediatric tele-cardiology service for district hospitals had reduced cost (24), home based tele-monitoring was found to be associated with improvements in the composite endpoint of mortality and rate of hospitalizations (25).

### Ophthalmology

A retrospective study (26) had shown that diagnosis and management of strabismus using telemedicine presented a true clinical picture. Tele-ophthalmology screening studies (27,28) have shown potential benefits.
**Dermatology**
The large sample RCT\(^{(29)}\) on 631 subjects on Tele-dermatologic consultations has revealed reduced referrals to a dermatologist by 21%. A small sample RCT\(^{(30)}\) using Web-based consultations on parents of children with atopic dermatitis revealed no effect of supplementing traditional treatment for childhood dermatitis. A descriptive study using store-and-forward tele-dermatology reported that confidence ratings for Live Interactive and Store and Forward were statistically lower than In-Person examinations\(^{(31)}\).

**Summary of outcome of reported telemedicine approaches**
Regarding relationship of outcome between conventional methods and telemedicine approaches, improvements in results were observed in 11 (41%) of the studies, which included three\(^{(6,8,9)}\) from neurology, three\(^{(18,20,21)}\) from diabetes, all four\(^{(22-25)}\) from cardiology and one\(^{(29)}\) from dermatology. Comparable results were seen in 4 (15%) studies, which included three\(^{(14-16)}\) from psychiatry, and one\(^{(26)}\) from ophthalmology. Benefits to patients were reported in 9 (33%), which included six\(^{(1,7,8,10-13)}\) from neurology, one\(^{(17)}\) from psychiatry and two\(^{(27,28)}\) from ophthalmology. However three studies (11%) showed that tele-medicine approach did not provide an enhanced benefit. They included a study in diabetes where specialist tele-medicine intervention did not augment Chronic Care Model (CCM) in primary care\(^{(19)}\) and studies in dermatology where web based consultations had no effect of supplementing traditional treatment of childhood dermatitis. The dermatologists tested were more confident with in-person examinations than tele-dermatology.

**Discussion**
Majority of studies published on telemedicine during the last two years have focused on neurology with psychiatry, diabetes and cardiology, in that order, followed by ophthalmology and dermatology.

Neurology studies which included five RCTs show the usefulness of telemedicine in this discipline. These have been applied in fields of stroke, epilepsy and rehabilitation. In Psychiatry, studies were small sample descriptive in nature and hence the outcome may have not been represented fully. The RCTs performed in diabetes have indicated a promising use of telemedicine for needy patients however a small study had reported negative results. All studies in cardiology have indicated successful implementation of home based surveillance. Retrospective studies on ophthalmology have shown advantages of tele-ophthalmology screening. The RCTs carried out in dermatology revealed advantages but a small sample study has reported some disadvantages of tele-medical systems over in-person examination. This agrees with previous recommendation that large scale RCTs are necessary in identifying health outcomes\(^{(3)}\).

**Conclusions**
This review shows that most of the large sample high-end studies have confirmed advantages of telemedicine systems whereas small sample low-end studies have found it to be disadvantageous. It is necessary to perform further large sample randomized controlled trials on telemedicine interventions in all health related disciplines to confirm these results.
